

## Lecture 20 Minimum Spanning Trees

EECS 281: Data Structures & Algorithms

## The Minimum Spanning Tree Problem

- **Given:** edge-weighted, *undirected*, connected graph  $G = (V, E)$
- **Find:** subgraph  $T = (V, E')$ ,  $E' \subseteq E$  such that
  - All vertices are pair-wise connected
  - The sum of all edge weights in  $T$  is minimal
- See a cycle in  $T$ ?
  - Remove edge with highest weight
- Therefore,  $T$  must be a tree (no cycles)

3

## MST Quiz

1. Prove that a unique shortest edge must be included in every MST
2. Prove for second shortest edge
3. What about third shortest edge?
4. Show a graph with  $> 1$  MST
5. Show a graph and its MST which avoids *some* shortest edge
6. Show a graph where every longest edge must be in every MST

*without creating cycle with smaller ones*

9

## Prim's Algorithm

- Find an MST on edge-weighted, connected, undirected graphs
- Greedily select edges one by one and add to a growing sub-graph
- Grows a tree from a single vertex

13

## Prim's Algorithm

1. Initialize a tree with a single vertex, chosen arbitrarily from the graph
2. Grow the tree by one edge: of the edges that connect the tree to vertices not yet in the tree, find the minimum-weight edge, and add that vertex to the tree
3. Repeat step 2 (until all vertices are in the tree)

14

## Prim's Algorithm

- Given graph  $G = (V, E)$
- Start with 2 sets of vertices: 'innies' & 'outies'
  - 'Innies' are visited nodes (initially empty)
  - 'Outies' are not yet visited (initially  $V$ )
- Select first innie arbitrarily (root of MST)
- Repeat until no more outies
  - Choose outie ( $v'$ ) with smallest distance from any innie
  - Move  $v'$  from outies to innies
- Implementation issue: use linear search or PQ?

15

## Prim: Data structures

- A vector of classes or structures
- For each vertex  $v$ , record:
  - $k_v$ : Has  $v$  been visited? (initially **false** for all  $v \in V$ )
  - $d_v$ : What is the minimal edge weight to  $v$ ? (initially  $\infty$  for all  $v \in V$ , except  $v_r = 0$ )
  - $p_v$ : What vertex precedes (is parent of)  $v$ ? (initially **unknown** for all  $v \in V$ )

16

## Implementing Prim's

- Implement in the order listed:
  - 1: Loop over all vertices: find smallest false  $k_v$
  - 2: Mark  $k_v$  as true
  - 3: Loop over all vertices: update false neighbors of  $k_v$
- Common Mistake: Set the first vertex to true outside the loop
- Reordering this can result in a simple algorithm that simply doesn't work

18

## MST This! (Prim's)

Using Prim's; start at node A

$v$	$K_v$	$D_v$	$p_v$
A	F	0	-
B	F	$\infty$	-
C	F	$\infty$	-
D	F	$\infty$	-
E	F	$\infty$	-

27

## Complexity – Linear Search

Loop  $v$  times:

$|V|$  times

1. From the set of vertices for which  $k_v$  is false, select the vertex  $v$  having the smallest tentative distance  $d_v$ .
2. Set  $k_v$  to true.  $O(1)$   $O(|V|)$
3. For each vertex  $w$  adjacent to  $v$  for which  $k_w$  is false, test whether  $d_w$  is greater than distance  $(v, w)$ . If it is, set  $d_w$  to distance  $(v, w)$  and set  $p_w$  to  $v$ .

Most at this vertex:  $O(|V|)$ . Cost of each:  $O(1)$ .

30

## Prim's (Heap) Algorithm

Algorithm Prim's\_Heaps( $G, s_0$ )

//Initialize

$n = |V|$

$O(1)$

create\_table( $n$ ) //stores  $k, d, p$

$O(V)$

create\_pq() //empty heap

$O(1)$

table[ $s_0$ ]. $d = 0$

$O(1)$

insert\_pq(0,  $s_0$ )

$O(1)$

31

## Prim's (Heap) Algorithm

while (!pq.isEmpty())

$O(E)$

$v_0 = \text{getMin}()$  //heap top() & pop()

$O(\log E)$

if (!table[ $v_0$ ]. $k$ ) //not known

$O(1)$

table[ $v_0$ ]. $k = \text{true}$

$O(1)$

for each  $v_i \in \text{Adj}[v_0]$

$O(1 + E/V)$

if (!table[ $v_i$ ]. $k$ )

$O(1)$

distance = weight( $v_0, v_i$ )

$O(1)$

if (distance < table[ $v_i$ ]. $d$ )

$O(1)$

table[ $v_i$ ]. $d = \text{distance}$

$O(1)$

table[ $v_i$ ]. $p = v_0$

$O(1)$

insert\_pq(distance,  $v_i$ )

$O(\log E)$

32

## Complexity – Heaps

Repeat until the PQ is empty:  $|E|$  times

1. From the set of vertices for which  $k_v$  is false, select the vertex  $v$  having the smallest tentative distance  $d_v$ .
2. Set  $k_v$  to true.  $O(1)$   $O(\log |E|)$
3. For each vertex  $w$  adjacent to  $v$  for which  $k_w$  is false, test whether  $d_w$  is greater than distance  $(v, w)$ . If it is, set  $d_w$  to distance  $(v, w)$  and set  $p_w$  to  $v$ .

Most at this vertex:  $O(|V|)$ . Cost of each:  $O(\log |E|)$ .

Note: Visits every edge once (over all iterations) =  $O(|E|)$ .

33

## Prim's: Complexity Summary

- $O(V^2)$  for the simplest nested-loop implementation
- $O(E \log E)$  with heaps  $\rightarrow |V|-1$  and usually much larger (if dense)
- Is this always faster?
- Think about the complexity of the PQ version for dense versus sparse graphs

34

## Kruskal's Algorithm

- Find an MST on edge-weighted, connected, *undirected* graphs
- Greedily select edges one by one and add to a growing sub-graph
- Grows a forest of trees that eventually merges into a single tree

37

## Kruskal's Algorithm

1. Presort all edges:  $O(E \log E) \approx O(E \log V)$  time
  2. Try inserting in order of increasing weight
  3. Some edges will be discarded so as not to create cycles
- Initial edges may be disjoint
    - Kruskal's grows a forest (union of disjoint trees)

38

## Kruskal's Algorithm

## Kruskal's Algorithm

43

## Kruskal's Algorithm

44

## Kruskal: Complexity Analysis

- Sorting takes  $O(E \log E)$ 
  - Happens to be the bottleneck of entire algorithm
- Remaining work: a loop over  $E$  edges
  - Discarding an edge is trivial  $O(1)$
  - Adding an edge is easy  $O(1)$
  - Most time spent testing for cycles  $O(?)$
  - Good news: takes less than  $\log E \approx \log V$
- Key idea: if vertices  $k$  and  $j$  are *already* connected, then a new edge would create a cycle
  - Only need to maintain disjoint sets

45

## Maintaining Disjoint Sets

- $N$  locations with no connecting roads
- Roads are added one by one
  - Distances are unimportant (for now)
  - Connectivity is important
- Want to connect cities ASAP
  - Redundant roads would slow us down

**Q: For two cities  $k$  and  $j$ , would road  $(k, j)$  be redundant?**

**A: Use a Union-Find data structure.**

46

## MST Summary

- MST is lowest-cost sub-graph that
  - Includes all nodes in a graph
  - Keeps all nodes connected
- Two algorithms to find MST
  - Prim: iteratively adds closest node to current tree – very similar to Dijkstra,  $O(V^2)$  or  $O(E \log E)$
  - Kruskal: iteratively builds forest by adding minimal edges,  $O(E \log E)$
- For dense  $G$ , use the nested-loop Prim variant
- For sparse  $G$ , Kruskal is faster
  - Relies on the efficiency of sorting algorithms
  - Relies on the efficiency of union-find
